

Netflix Content Analysis

Executive Summary

Prepared by: Tenzin Dugda

Role: Data Analyst Portfolio Project

Date: July 2026

Executive Overview

The purpose of this analysis was to evaluate Netflix's content library to identify trends in content distribution, release history, content ratings, geographic representation, and data quality. The analysis used SQL for data extraction and Google Sheets for visualization.

The dataset contains **8,807 titles**, including **6,131 movies** and **2,676 TV shows**, spanning **748 countries or country combinations** and **4,528 directors**.

Key Findings

1. Movies represent about **70%** of the catalog.
2. Content additions accelerated after **2015**.
3. The United States contributes the largest number of titles, followed by India, the United Kingdom, Japan, and South Korea.
4. TV-MA is the most common rating.
5. A relatively small group of directors accounts for multiple Netflix titles.

Data Quality Assessment

Missing metadata identified:

- Director: 2,634
- Cast: 825
- Country: 831
- Date Added: 10
- Rating: 4
- Duration: 3

The largest issue is missing director information, which could impact reporting and recommendation analysis.

Business Recommendations

- Improve metadata quality by filling missing director, cast, and country information.
- Continue investing in successful international markets.
- Monitor content rating distribution to maintain audience diversity.
- Continue tracking release trends to support licensing and production decisions.

Limitations

Some records contain multiple countries in a single field and were analyzed as one value. The dataset is a snapshot and may not reflect Netflix's current catalog.

Conclusion

This project demonstrates the complete analytics workflow from SQL analysis to dashboard creation and executive reporting. The findings highlight a movie-focused catalog, strong growth after 2015, significant international representation, and opportunities to improve metadata quality.
